Abstract

Fire-retardant (FR) textiles are essential in personal protective equipment (PPE) for firefighters, industrial workers, military personnel, and emergency responders exposed to extreme heat and flames[4][5]. Their effectiveness relies on **structural integrity** and **uniform flame-resistant coatings**, as even minor defects-such as broken fibres, coating gaps, or contamination-can compromise safety[1][3].

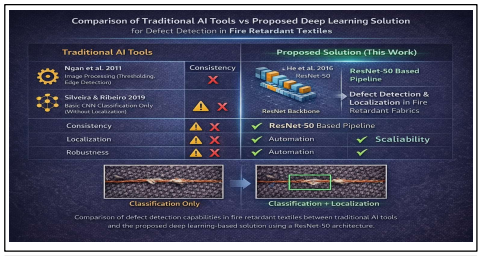
Currently, quality inspection is largely **manual**, making it prone to **fatigue, subjective judgment, inconsistent accuracy, and poor scalability**. This often leads to defective materials passing undetected into the supply chain.
To address this, the paper proposes an **AI-driven defect detection[1] and localization system** using a Convolutional Neural Network (CNN) based on the **ResNet-50 architecture** pre-trained on ImageNet and fine-tuned on the **AITEX Fabric Defect Dataset** (4,500+ annotated images across seven defect categories[2].

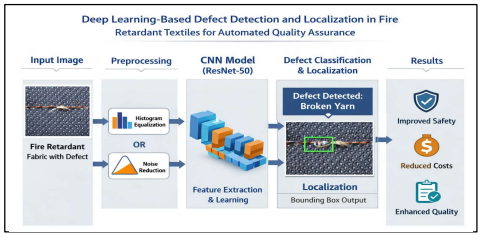
Preprocessing techniques such as **histogram equalization** and **Gaussian filtering** enhance image quality, while **data augmentation** (flipping, rotation, cropping) improves model generalization.
The system performs **defect classification (Softmax)** and **spatial localization (Grad-CAM heatmaps)**, enabling precise identification of defect type and location. Results show **94% accuracy**, with **92% precision**, **91% recall**, and an **F1-score of 0.93**-about **18% improvement** over traditional methods.

Implementing this system can **reduce quality control costs by 40-60%**, **eliminate human error**, and ensure reliable FR textiles. It also supports compliance with **ISO 11612** and **NFPA 2112**, demonstrating the impact of AI in modern textile inspection[4][5]

Introduction

Fire-retardant textiles form the first line of defence for firefighters, military personnel, and workers in hazardous environments. Any defect in the protective coating - such as broken fibres, contamination, or weave irregularities - can catastrophically reduce flame resistance, directly endangering human lives.
Current quality assurance processes depend heavily on trained human inspectors who visually examine fabric samples. This approach suffers from subjectivity, inspector fatigue, high false-negative rates, and limited scalability. As production volumes increase, manual inspection becomes a critical bottleneck.
Deep learning-based computer vision offers a transformative solution. By training convolutional neural networks on large annotated datasets, it becomes possible to detect and localize fabric defects with superhuman consistency and speed. This work addresses the urgent need for a reliable, automated, and standards-compliant inspection pipeline for FR textiles used in life-critical PPE.
Defect Categories: Broken Ends · Broken Picks · Contamination Spots · Holes · Nep · Weft Curling · Knots



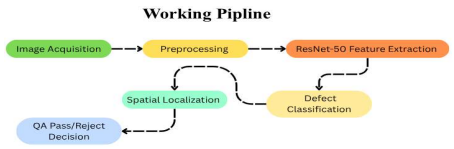


Methods and Materials

Dataset:
The AITEX Fabric Defect Dataset was used, comprising over 4,500 high-resolution annotated fabric images spanning seven defect categories. Images include both defective and defect-free samples to support balanced training.
Image Preprocessing:
- Histogram Equalization - enhances contrast to reveal subtle surface defects
- Gaussian Noise Filtering - removes sensor noise for cleaner feature maps
- Normalization and data augmentation (random flip, rotation, cropping) to improve model generalization.

Model Architecture - ResNet-50: A 50-layer deep residual network with skip connections was selected for its proven ability to learn fine-grained visual features without vanishing gradient problems. The model was pre-trained on ImageNet and fine-tuned on the AITEX dataset. The final classification head outputs probabilities across seven defect classes via Softmax activation[2].

Spatial Localization: Gradient-weighted Class Activation Mapping (Grad-CAM) was applied to generate heatmaps that highlight defect regions within the fabric image, enabling precise localization alongside classification.



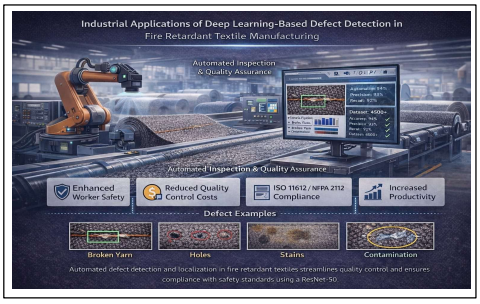
Results & Discussion

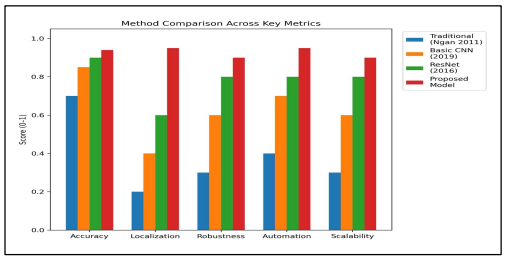
The proposed ResNet-50[2] based system was evaluated on the AITEX test set and achieved the following performance:

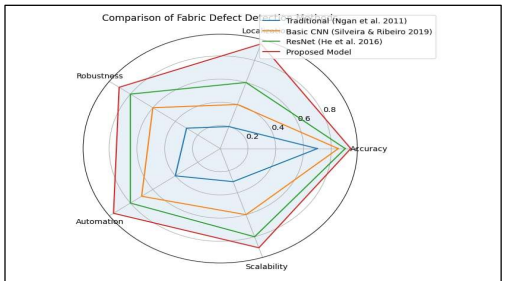
Metric	Score
Accuracy	94%
Precision	92%
Recall	91%
F1 Score	0.93

Per-Class Detection Accuracy:
- Broken Ends : 96%
- Contamination Spots : 93%
- Broken Picks : 91%
- Weft Curling / Knots : 89%

The ResNet-50 model outperformed traditional image processing methods by approximately 18% in overall detection accuracy. Grad-CAM spatial localization successfully highlighted defect regions with high fidelity, enabling targeted quality review rather than full batch rejection. The system demonstrated robust performance even under variable lighting and fabric texture conditions. These results confirm the viability of deep learning as a replacement[2][3].







Comparative analysis of traditional methods, early CNN approaches, and the proposed ResNet-based system across key performance dimensions.

Conclusions

This work demonstrates that deep learning-based computer vision can effectively automate defect detection and localization in fire-retardant textiles with high accuracy and reliability[3]
Key outcomes:-
- 94% overall detection accuracy achieved using ResNet-50 across seven defect categories.
- Spatial localization via Grad-CAM heatmaps enables precise defect pinpointing, not just pass/fail classification.
- Significant reduction in quality control cost and inspection time, supporting scalable manufacturing integration.
- Sub-standard FR textiles are identified and rejected before reaching life-critical environments.
- The system supports compliance with ISO 11612 and NFPA 2112 through consistent, auditable inspection[4][5].

Future work will focus on real-time edge deployment using lightweight model variants, expansion to a broader range of textile defect types, and integration with smart factory IoT infrastructure for end-to-end automated quality assurance.

Industrial Application

This system is directly applicable across multiple high-stakes industries:

Firefighter PPE Manufacturing : Inline quality assurance for turnout gear and proximity suits, ensuring no defective fabric reaches field deployment.

Industrial Workwear Production : Automated inspection of flash-fire protection garments used in oil, gas, and chemical processing sectors.

Defence & Military : Quality validation of flame-resistant uniforms and combat protective clothing for armed forces.

Arc Flash Protection : Verification of electrical arc-rated textiles for utility and power sector workers.

Laboratory & Research : Accelerated material testing and compliance verification pipelines for FR textile developers.[4][5]

Integration into existing conveyor-belt inspection lines with camera modules enables real-time batch rejection before packaging. Estimated quality control cost reduction: 40-60% compared to manual inspection. The system also generates auditable digital inspection records, supporting regulatory compliance with ISO 11612 and NFPA 2112.[4][5]
